э

erc

The treatment scenario

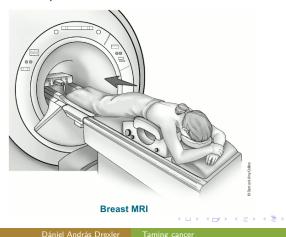

The patient visits the doctor in fixed intervals. We will call this interval the sampling time, denote it by T_s and measure it in days.

erc

The treatment scenario

At each visit, the doctor examines the patient, and we suppose that as a result all internal states (tumor volume, endothelial volume, inhibitor serum level) become available.

< ロ > < 同 > < 回 > < 回 >

erc

The treatment scenario

The doctor defines the desired tumor volume for the next investigation. The minimal amount of drug injection that is required to reach the desired tumor volume is calculated using the tumor growth model and the information acquired from the measurements in the previous step using an optimization algorithm.

イロト イポト イヨト イヨト

erc

The optimization problem

- At the kth investigation (kth step) we know the internal states of the system x₁[k] := x₁(kT_s), x₂[k] := x₂(kT_s), and g[k] := g(kT_s).
- The desired tumor volume for the next step is denoted by $x_{1,d}[k+1]$.
- We are looking for the minimal amount of injection u[k] such that the tumor volume in the next step is less than or equal to the desired tumor volume, i.e. $x_1[k+1] \le x_{1,d}[k+1]$.

Main concept Discrete therapy as an optimization proble Continuous therapy

erc

シママ 11/46

The optimization algorithm

Input: The initial values $x_1[k]$, $x_2[k]$ and g[k]. The *TOL* accuracy of the solution. The desired tumor volume $x_{1,d}[k+1]$. The maximal drug injection *UMAX*.

Result: The minimal drug dosage u[k] that is required to reach the desired tumor volume in the next step.

(日)

erc

The optimization algorithm

```
Let u_{max} = UMAX and u_{min} = 0
while u_{\rm max} - u_{\rm min} > TOL do
   u = (u_{max} - u_{min})/2 Calculate the tumor volume in the next
   time instant (k+1)T_s by solving the initial value problem on
   time interval [kT_s, (k+1)T_s] defined by the model with initial
   values x_1[k], x_2[k], g[k] + u; denote it by x_1[k+1]
   if x_1[k+1] > x_{1,d}[k+1] then
      u_{\min} := u
   else
      u_{\max} := u
   end
end
```

Main concept Discrete therapy as an optimization proble Continuous therapy

erc

13/46

The previous algorithm is a binary search algorithm, thus it only works if the model output is monotonous in the input.

Theorem

The output of the Hahnfeldt-model with linear pharmakokinetics is monotonous in the input.

33/46

Model equations

Model reduction

$$\dot{x}_1 = ax_1 - nx_1 - b \frac{x_1 x_3}{ED_{50} + x_3} \dot{x}_2 = nx_1 + b \frac{x_1 x_3}{ED_{50} + x_3} \dot{x}_3 = -c \frac{x_3}{K_B + x_3} - b_\kappa \frac{x_1 x_3}{ED_{50} + x_3} + u$$

The second equation can be omitted since the other equations do not depend on x_2 .

Model equations **The closed-loop system** The equilibria of the closed-loop system

Model equations, closed-loop system

Planar system

$$\begin{aligned} \dot{x}_1 &= ax_1 - nx_1 - b \frac{x_1 x_3}{ED_{50} + x_3} \\ \dot{x}_3 &= -c \frac{x_3}{K_B + x_3} - b_\kappa \frac{x_1 x_3}{ED_{50} + x_3} + u, \end{aligned}$$

Closed-loop system

The applied control law is state feedback, i.e. $u = k_1x_1 - k_3x_3$. Thus, the model of the closed-loop system is

$$\dot{x}_1 = ax_1 - nx_1 - b \frac{x_1 x_3}{ED_{50} + x_3} \\ \dot{x}_3 = -c \frac{x_3}{K_B + x_3} - b_\kappa \frac{x_1 x_3}{ED_{50} + x_3} + k_1 x_1 - k_3 x_3.$$

Model equations The closed-loop system The equilibria of the closed-loop system

< ロ > < 同 > < 回 > < 回 >

Table of contents

Introduction

- Main concept
- Discrete therapy as an optimization problem
- Continuous therapy

2 Tumor model and analysis

- Model equations
- The closed-loop system
- The equilibria of the closed-loop system

Vlodel equations The closed-loop system The equilibria of the closed-loop system

• • • • • • • • • • • •

Equilibria of the closed-loop system

First equilibrium

$$x_1^* = 0, x_3^* = 0.$$

The eigenvalues of the linearized system are

$$\lambda_1 = -ED_{50}\frac{c+k_3K_B}{K_B} < 0$$

$$\lambda_2 = ED_{50}(a-n).$$

If a - n > 0, then the tumor grows (the growth rate is larger than the necrotic rate), in this case this point is a saddle (the tumor grows, the drug depletes).

If a - n < 0, then the tumor shrinks (the growth rate is smaller than the necrotic rate), in this case this point is a stable node.

Model equations The closed-loop system The equilibria of the closed-loop system

・ ロ ト ・ 同 ト ・ 国 ト ・ 国 ト ・

э

Equilibria of the closed-loop system

Second equilibrium

$$x_1^* = 0, x_3^* = -\frac{c + k_3 K_B}{k_3} < 0.$$

This equilibrium is physiologically unfeasible, since the inhibitor serum level can not be negative.

Model equations The closed-loop system The equilibria of the closed-loop system

Equilibria of the closed-loop system

Third equilibrium

$$x_3^* = -\frac{ED50(a-n)}{a-b-n}$$

The physiologically interesting case is when a - n > 0, i.e. the tumor does not heal spontaneously. The equilibrium point for x_3^* is positive if and only if

$$a-b-n<0.$$

It has been shown earlier that this is the condition for the drug to be effective against tumor.

Model equations The closed-loop system The equilibria of the closed-loop system

æ

Equilibria of the closed-loop system

Third equilibrium

$$x_1^* = \frac{x_{1,n}}{x_{1,d}}$$

with

Vlodel equations The closed-loop system **The equilibria of the closed-loop system**

erc

40/46

Equilibria of the closed-loop system

Third equilibrium

Taking into account the previous conditions, this equilibrium is positive if either

$$k_1 > b_{\kappa} \frac{a-n}{b}$$

$$k_3 > c \frac{a-b-n}{aED_{50} - aK_B + bK_B - ED_{50}n + K_Bn}$$

or

$$k_1 < b_{\kappa} \frac{a-n}{b}$$

$$k_3 < c \frac{a-b-n}{aED_{50} - aK_B + bK_B - ED_{50}n + K_Bn}.$$

Model equations The closed-loop system The equilibria of the closed-loop system

erc

・ロト ・四ト ・ヨト ・ヨト

э

41/46

Equilibria of the closed-loop system

Third equilibrium

If the Jacobian J is a 2×2 matrix, then the eigenvalues of the Jacobian are

$$\lambda_{1,2} = rac{\mathsf{Tr}(J) \pm \sqrt{\mathsf{Tr}(J)^2 - 4\,\mathsf{Det}(J)}}{2}.$$

In order to have eigenvalues with negative real parts (i.e., to guarantee that the equilibrium point is stable) the parameters should be chosen such that

$$\begin{array}{rcl} {\sf Tr}(J) &< 0\\ {\sf Det}(J) &> 0. \end{array}$$

Model equations The closed-loop system The equilibria of the closed-loop system

Equilibria of the closed-loop system

Third equilibrium

The equilibrium is stable iff

$$k_1 > b_{\kappa} rac{a-n}{b}$$

 $k_3 > rac{\varphi}{\omega}$

$$\varphi = c(-a+b+n)^{2}(a^{2}b_{\kappa}(ED_{50}-K_{B}) + b^{2}k_{1}K_{B} + 2ab_{\kappa}(-ED_{50}+K_{B})n + b_{\kappa}(ED_{50}-K_{B})n^{2})$$

$$\omega = (a(ED_{50}-K_{B}) + bK_{B} + (-ED_{50}+K_{B})n)^{2}(a^{2}b_{\kappa} + b^{2}k_{1} - 2ab_{\kappa}n + b_{\kappa}n^{2}).$$

Model equations The closed-loop system The equilibria of the closed-loop system

Equilibria of the closed-loop system

Decreasing the third equibrium tumor volume

$$x_1^* = \frac{x_{1,n}}{x_{1,d}}$$

$$\partial_{k_3} x_{1,n} = bED_{50}(a-n)(bK_B - a(-ED_{50} + K_B)) + (-ED_{50} + K_B)n) > 0$$

Decreasing k_3 decreases equilibrium tumor volume, however, the closed-loop system may become unstable.

Control input

$$u = k_1 x_1 - k_3 x_3.$$

Decreasing k_3 results in increasing control input.

Model equations The closed-loop system The equilibria of the closed-loop system

Equilibria of the closed-loop system

Decreasing the third equibrium tumor volume

$$x_1^* = \frac{x_{1,n}}{x_{1,d}}$$

$$\partial_{k_1} x_{1,d} = b(-a+b+n)(a(ED_{50}-K_B)+bK_B) + (-ED_{50}+K_B)n) > 0$$

Increasing k_1 means decreasing equilibrium tumor volume, no conflict with stability.

Control input

$$u = k_1 x_1 - k_3 x_3.$$

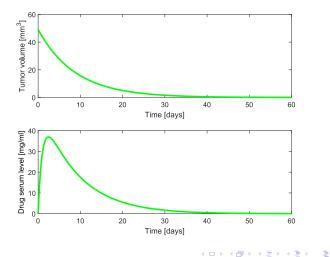

Increasing k_1 means increasing control input.

Model equations The closed-loop system The equilibria of the closed-loop system

45/46

Equilibria of the closed-loop system
