To approximate the solution of an IVP

$$\frac{dx}{dt} = f(t,x), \quad x(t_0) = x_0, \quad t \in [t_0, t_f]$$

a k-step method uses k previous approximations $x_{n-i} \approx x(t_{n-i}), \quad i = 1:k,$

$$x_n = \alpha_{k-1}x_{n-1} + \dots + \alpha_0x_{n-k} + h_n(\beta_k f_n + \dots + \beta_0 f_{n-k})$$

$$h_i = t_i - t_{i-1}, \qquad f_i = f(t_i, x_i)$$

Adaptivity: choose h_n to attain prescribed accuracy.

Lund Institute of Technology/Lund University < ロ > < 合 > < 主 > < 主 > シ へ ()

Adaptivity

Why do we need adaptivity?

- accuracy
- efficiency
- stability

Adaptivity

Why do we need adaptivity?

- accuracy
- efficiency
- stability

Adaptivity aims to control the error at each integration step

- estimate the local error
- choose h_n to keep the error at an assigned value (tolerance)

Order of a multistep method

Approximation: $x_n \approx x(t_n)$ and $x'_n \approx f(t_n, x(t_n))$

When is a method said to be of order q?

Lund Institute of Technology/Lund University < ロ > < 合 > < 主 > < 主 > シ へ ()

Order of a multistep method

Approximation: $x_n \approx x(t_n)$ and $x'_n \approx f(t_n, x(t_n))$

When is a method said to be of order q?

For any ODE whose solution x is a polynomial of degree q, the method recovers the exact solution:

$$x_n = x(t_n)$$

Lund Institute of Technology/Lund University < □ → < □ → < ≧ → < ≧ → < ≧ → ○ < ⊘

Order of a multistep method

Approximation: $x_n \approx x(t_n)$ and $x'_n \approx f(t_n, x(t_n))$

When is a method said to be of order q?

For any ODE whose solution x is a polynomial of degree q, the method recovers the exact solution:

$$x_n = x(t_n)$$

Lower order methods \rightarrow larger stability regions Higher order methods \rightarrow allow larger step-sizes

Lund Institute of Technology/Lund University

Polynomial of a method with k steps and order q

To advance a step of an order q method we construct a *method* polynomial $P_n \in \mathcal{P}_q$ using previously calculated values and define

$$x_n = P_n(t_n)$$

The polynomial of a k-step method will depend on the last k approximated solutions and their derivatives.

Maximal order multistep methods

Three types of high order *k*-step methods (Dahlquist 1st barrier):

type	max order
implicit	k+1
explicit	k

For Nonstiff problems:

- **E**_k: *Explicit k-step*, order q = k, e.g. Adams–Bashforth
- ▶ I_k^+ : Implicit k-step, order q = k + 1, e.g. Adams-Moulton

For **Stiff** problems:

▶ I_k : Implicit k-step, order q = k, e.g. BDF methods

Lund Institute of Technology/Lund University

Solution: slack conditions

Do not insist on interpolation/collocation conditions; allow a slack:

$$s_{n-i} = P_n(t_{n-i}) - x_{n-i}$$
 (state slack)
 $s'_{n-i} = \dot{P}_n(t_{n-i}) - x'_{n-i}$ (derivative slack)

and combine each slack pair into a slack balance condition:

$$a s_{n-i} + b h_{n-i} s_{n-i}' = 0$$

Lund Institute of Technology/Lund University < ロ > < 合 > < 主 > < 主 > シ へ ()

Solution: slack conditions

Do not insist on interpolation/collocation conditions; allow a slack:

$$s_{n-i} = P_n(t_{n-i}) - x_{n-i}$$
 (state slack)
 $s'_{n-i} = \dot{P}_n(t_{n-i}) - x'_{n-i}$ (derivative slack)

and combine each slack pair into a slack balance condition:

$$a\,s_{n-i}+b\,h_{n-i}s_{n-i}'=0$$

simplified to

$$\cos\theta \, s_{n-i} + \sin\theta \, h_{n-i} s_{n-i}' = 0, \quad \theta \in (-\pi/2, \pi/2]$$

Lund Institute of Technology/Lund University

An application to SSP multistep methods

Strong stability preserving methods avoid instabilities when solving ODEs arising from the semi-discretization of hyperbolic PDEs.

$$\dot{y} = F(y), \quad y(t_0) = y_0, \quad t \in [t_0, t_f]$$

with the property

$$\|y + hF(y)\| \le \|y\|$$
 for all y and $h \le h^*$

solved by explicit multistep method

$$y_n = \sum_{i=1}^k (\alpha_i y_{n-i} + h\beta_i F(y_{n-i})), \text{ with } \alpha_i, \beta_i \ge 0$$

 $\mathsf{SSP} \text{ if } \|y_n\| \leq \max\{\|y_{n-1}\|, \dots, \|y_{n-k}\|\} \text{ for } 0 < h \leq Ch^*$

Lund Institute of Technology/Lund University

Explicit SSP multistep methods

- $\alpha_i, \beta_i \geq 0$
- ► $0 < h \leq Ch^*$
- SSP constant: $C = \min_{i} \{ \alpha_i / \beta_i \}$
- ▶ q < k
- Zero coefficients of fixed step-size formula should be preserved by variable step-size extension

Adaptive explicit SSP multistep methods: formulation for lower order methods that preserves pattern of zero coefficients

Lund Institute of Technology/Lund University

Formulation of optimal SSP methods

Procedure to construct optimal SSP(k, q) method

• Take
$$s_{n-1} = 0$$
 and $s'_{n-1} = 0$

► Take
$$s_{n-i} + h_{n-i} \frac{\beta_i}{\alpha_i} s'_{n-i} = 0$$
 whenever $\alpha_i \neq 0, 1 < i < k$

• Take
$$s_{n-k} = 0$$

• If
$$q$$
 is odd, also add $s'_{n-k} = 0$

The method parameters are $\tau_i = \beta_i / \alpha_i$

 Example of optimal explicit 8-step SSP method of order 5

Its nonzero coefficients:

$$\alpha_1 = \frac{1360}{4363}, \quad \alpha_4 = \frac{233}{2112}, \quad \alpha_5 = \frac{2323}{10831}, \quad \alpha_8 = \frac{896}{2465}$$
$$\beta_1 = \frac{275}{128}, \quad \beta_4 = \frac{1044}{1373}, \quad \beta_5 = \frac{6661}{4506}, \quad \beta_8 = \frac{1781}{5144}$$

$$s_{n-1} = 0$$

$$s'_{n-1} = 0$$

$$s_{n-4} + h_{n-4}\tau_4 s'_{n-4} = 0$$

$$s_{n-5} + h_{n-5}\tau_5 s'_{n-5} = 0$$

$$s_{n-8} = 0$$

$$s'_{n-8} = 0$$

$$\tau_4 = \beta_4/\alpha_4, \quad \tau_5 = \beta_5/\alpha_5$$

Consequence of σ not satisfying the strict root condition?

Instability in algebraic variables

Implicit methods with roots of $\sigma(\zeta)$ inside the unit circle

- e.g. BDF (k-step, order k)
- no implicit k-step method of order k + 1 (e.g. Adams-Moulton)

Consequence of σ not satisfying the strict root condition?

Instability in algebraic variables

Implicit methods with roots of $\sigma(\zeta)$ inside the unit circle

e.g. BDF (k-step, order k)

 no implicit k-step method of order k + 1 (e.g. Adams-Moulton)

Solution: β -blocking

- \blacktriangleright Modify σ to move roots into unit circle
- New operator σ + τ, with roots inside unit circle, should only affect algebraic variables
- au should disturb order as little as possible

Construction of β -blocker operator

- Reduce order as little as possible by taking $\tau = c \nabla^k$
- Keep σ for differential variables
- $\sigma + \tau$ for algebraic variables

Order:

k + 1 for differential variable, k for algebraic variable

β -blocking published 1997–2000 as fixed step-size technique

Standard formulation of index-2 Euler-Lagrange DAE

$$P_n \in \mathcal{P}_{k+1}$$

$$P'_{n}(t_{n}) = f(P_{n}(t_{n})) - G(P_{n}(t_{n}))^{T} \lambda_{n}$$

$$P_{n}(t_{n-1}) = x_{n-1}$$

$$P'_{n}(t_{n-1}) = f(x_{n-1}) - G(x_{n-1})^{T} \lambda_{n-1}$$

$$\cos \theta_{j-1} s_{n-j} + h_{n-j} \sin \theta_{j-1} (s'_{n-j} + G(x_{n-j})^{T} \lambda_{n-j}) = 0$$

$$g(P_{n}(t_{n})) = 0$$

for j = 2 : k.

Then
$$x_n := P_n(t_n)$$
.

 β -blocked formulation of index-2 Euler-Lagrange DAE

$$P_n \in \mathcal{P}_{k+1}$$
 and $Q_n \in \mathcal{P}_k$

$$P'_{n}(t_{n}) = f(P_{n}(t_{n})) - G(P_{n}(t_{n}))^{T}(Q_{n}(t_{n}) + \hat{c} h_{n-1}^{k}Q_{n}^{(k)}(t_{n}))$$

$$P_{n}(t_{n-1}) = x_{n-1}$$

$$P'_{n}(t_{n-1}) = f(x_{n-1}) - G(x_{n-1})^{T}Q_{n}(t_{n-1})$$

$$Q_{n}(t_{n-j}) = \lambda_{n-j}$$

$$\cos \theta_{j-1}s_{n-j} + h_{n-j}\sin \theta_{j-1}(s'_{n-j}) + G(x_{n-j})^{T}\lambda_{n-j}) = 0$$

$$g(P_{n}(t_{n})) = 0$$

for j = 2 : k, $\hat{c} = c \beta_k^{-1}$.

Set
$$x_n := P_n(t_n)$$
 and $\lambda_n := Q_n(t_n)$.
